Centsible

Personal Finance Tracker

Wireframe / Prototype

The non-interactive prototype shows the planned visual design for the Centsible application. It includes multiple main screens such as the Dashboard, Transactions, Budget, Reports, and Bills & Subscriptions pages. Each screen follows a consistent dark theme with a left-side navigation menu, clear page titles, financial summary cards, charts, tables, and action buttons.

The Dashboard page gives users a quick overview of their current balance, income, expenses, savings progress, and recent transactions. The Transactions page displays financial activity in a table format with categories and transaction details. The Budget page shows budget progress using summary cards and visual progress bars. The Reports page includes charts and spending summaries to help users understand their financial habits. The Bills & Subscriptions page allows users to view upcoming bills, subscriptions, amounts, and due dates.

This prototype is non-interactive, meaning it shows how the application will look, but the buttons, charts, and navigation links do not actually function. Its purpose is to demonstrate the layout, visual style, and overall user interface before development begins.

New Document: System Design / Feature Dependency Diagram

Design Summary

The System Design and Feature Dependency Diagram shows the main structure of the Centsible application and how each part of the system connects together. The diagram includes the major features of the application, such as User Registration & Authentication, Transactions, Budgeting, Bills & Subscriptions, and Dashboard & Reporting. It also shows the tools and frameworks being used, including React for the UI, SQL for the database, environment variables for security, Express middleware, JWT, bcrypt, and Zod for validation. The diagram explains how users will register and log in, how transactions will be added and stored, how budgets will calculate spending limits, and how bills and subscriptions will be tracked. It also shows that the dashboard and reports will use the transaction, budget, and bill data to display balances, income versus expenses, recent transactions, budget progress, and monthly spending charts.

Design Rationale

This design was created to show how the main features of the application depend on each other before development begins. Authentication is separated from the financial features because users need to securely register and log in before accessing their data. Transactions are important because they provide the financial data used by budgeting, bills, and reporting. Budgeting uses transaction data to calculate current spending and compare it to the user's monthly limit. The dashboard and reporting section is placed near the end because it depends on information from the other parts of the system. This makes sense because the dashboard is mainly used to summarize the user's financial activity. The framework section was included to show what technologies support each feature. Overall, the design helps organize the application into clear sections and makes it easier to understand how data will move through the system.
